

# 99 questions/1 to 10

< 99 questions

This is part of Ninety-Nine Haskell Problems, based on **Ninety-Nine Prolog Problems** and **Ninety-Nine Lisp Problems**:

## Problem 1

(\*) Find the last element of a list.

(Note that the Lisp transcription of this problem is incorrect.)

Example in Haskell:

```
λ> myLast [1,2,3,4]
4
λ> myLast ['x','y','z']
'z'
```

Solutions

## Problem 2

(\*) Find the last but one element of a list.

(Note that the Lisp transcription of this problem is incorrect.)

Example in Haskell:

```
λ> myButLast [1,2,3,4]
3
λ> myButLast ['a'..'z']
'y'
```

Solutions

## Problem 3

(\*) Find the K'th element of a list. The first element in the list is number 1.

Example:

```
* (element-at '(a b c d e) 3)
c
```

Example in Haskell:

```
λ> elementAt [1,2,3] 2
2
λ> elementAt "haskell" 5
'e'
```

Solutions

## Problem 4

(\*) Find the number of elements of a list.

Example in Haskell:

```
λ> myLength [123, 456, 789]
3
λ> myLength "Hello, world!"
13
```

Solutions

## Problem 5

(\*) Reverse a list.

Example in Haskell:

```
λ> myReverse "A man, a plan, a canal, panama!"
"!amanap ,lanac a ,nalp a ,nam A"
λ> myReverse [1,2,3,4]
[4,3,2,1]
```

Solutions

## Problem 6

(\*) Find out whether a list is a palindrome. A palindrome can be read forward or backward; e.g. (x a m a x).

Example in Haskell:

```
λ> isPalindrome [1,2,3]
False
λ> isPalindrome "madamimadam"
True
λ> isPalindrome [1,2,4,8,16,8,4,2,1]
True
```

Solutions

## Problem 7

(\*\*) Flatten a nested list structure.

Transform a list, possibly holding lists as elements into a 'flat' list by replacing each list with its elements (recursively).

Example:

```
* (my-flatten '(a (b (c d) e)))
(A B C D E)
```

Example in Haskell:

We have to define a new data type, because lists in Haskell are homogeneous.

```
data NestedList a = Elem a | List [NestedList a]

λ> flatten (Elem 5)
[5]
λ> flatten (List [Elem 1, List [Elem 2, List [Elem 3, Elem 4], Elem 5]])
[1,2,3,4,5]
λ> flatten (List [])
[]
```

Solutions

## Problem 8

(\*\*) Eliminate consecutive duplicates of list elements.

If a list contains repeated elements they should be replaced with a single copy of the element. The order of the elements should not be changed.

Example:

```
* (compress '(a a a b c c a a d e e e e))
(A B C A D E)
```

Example in Haskell:

```
λ> compress "aaabccaadeeee"
"abcade"
```

Solutions

## Problem 9

(\*\*) Pack consecutive duplicates of list elements into sublists. If a list contains repeated elements they should be placed in separate sublists.

Example:

```
* (pack '(a a a b c c a a d e e e e))
((A A A A) (B) (C C) (A A) (D) (E E E E))
```

Example in Haskell:

```
λ> pack ['a', 'a', 'a', 'a', 'b', 'c', 'c', 'a', 'a', 'd', 'e', 'e', 'e', 'e', 'e']
["aaaa", "b", "cc", "aa", "d", "eeee"]
```

Solutions

## Problem 10

(\*) Run-length encoding of a list. Use the result of problem P09 to implement the so-called run-length encoding data compression method. Consecutive duplicates of elements are encoded as lists (N E) where N is the number of duplicates of the element E.

Example:

```
* (encode '(a a a a b c c a a d e e e e))
((4 A) (1 B) (2 C) (2 A) (1 D) (4 E))
```

Example in Haskell:

```
λ> encode "aaabccaadeeee"
[(4, 'a'), (1, 'b'), (2, 'c'), (2, 'a'), (1, 'd'), (4, 'e')]
```
